ABSTRACT

Aims: To investigate the catalytic activity of pyridine-2,6-dicarboxylic acid in the redox reaction of Cr(VI) and phenylsulfinyl acetic acid.

Study Design: The mechanism of the reaction was designed on the basis of the observed results of kinetic, spectral and substituent effect studies.

Place and Duration of Study: Laboratory of the Research Department of Chemistry, Aditanar College of Arts and Science, Tiruchendur, Tamil Nadu, India. September 2013 – January 2014.

Methodology: Phenylsulfinyl acetic acid and ten meta- and para-substituted phenylsulfinyl acetic acids essential for the present kinetic study were synthesized. The kinetic study was performed in 40% acetonitrile-60% H$_2$O medium under pseudo-first-order conditions by maintaining [PSAA] >>
1. INTRODUCTION

Pyridine-carboxylic acids occupy prime importance in research as they are excellent ligands [1] and good synths for supramolecular architectures and coordination polymers [2]. These ligands have structural adaptability to self-assemble into two or three dimensional frameworks either using hydrogen bonding or by polymerization. Pyridine mono- and di-carboxylic acids are prominent ligands from catalytic and crystal engineering point of view. Pyridine-2,6(dicarboxylic acid; catalytic activity; Michalis-Menten kinetics; substituent effect.

2. EXPERIMENTAL DETAILS

2.1 Materials

The substrates, PSAA and several meta- and para-substituted PSAs essential for the present kinetic study were synthesized [18] by the controlled oxidation of the corresponding phenylthio acetic acids using equimolar amount of H₂O₂. Then the samples were recrystallized from suitable solvents and stored in vacuum desiccator. Their melting points were determined and compared with the literature values [19]. The purity was also checked by LCMS. Potassium dichromate (Merck), sodium perchlorate (Merck), HClO₄ (Merck) and pyridine-2,6-dicarboxylic acid (SDs) were of AnalaR grade and the stock solutions were prepared using double distilled water. The solvent, acetonitrile was used after purification by literature method [20].

2.2 Kinetic Measurements

The reaction mixture, under the conditions [PSAA] >> [Cr(VI)] and [PDA] >> [Cr(VI)] was...
used for the kinetic runs throughout the experiment. Progress of the reaction was monitored by following the rate of disappearance of Cr(VI). The reaction mixture was scanned in the range 200-700 nm using UV-vis spectrophotometer at regular intervals to follow the gradual development of intermediate if any and product. The spectral changes associated with the PDA catalyzed oxidative decarboxylation of PSAA are shown in (Fig. 1).

The pseudo-first-order rate constant \( (k_1) \) for each kinetic run was evaluated from the slope of log OD vs. time by the method of least squares. The overall rate constant of the PDA catalyzed reaction is calculated using the eq. (1),

\[
    k_{ov} = \frac{k_1}{[PSAA]}^n
\]

where \( n \) is the order of the reaction with respect to PSAA and \( k_1 \) is the observed pseudo-first-order rate constant for the PDA catalyzed reaction. The precision of the \( k \) values is given in terms of 95% confidence limits of student’s t test.

2.3 Product Analysis

The reaction mixture in the stoichiometric condition was kept for 48 hours to ensure completion of the reaction. The solvent was then evaporated and extracted with ether. The ether layer was collected, dried over anhydrous sodium sulfate and the ether was removed by evaporation. IR and GC-MS analysis of the residue obtained from the ether extract confirm that methylphenyl sulfone is the only product of the reaction. IR spectrum shows strong bands at 1148 cm\(^{-1}\) and 1290 cm\(^{-1}\) characteristic of symmetric and asymmetric stretching respectively of \( \text{SO}_2 \) group [21].

The absorption spectra of the reaction mixture after completion exhibits two distinct peaks: one at 577 nm and another at 434 nm corresponding to \( ^4A_{2g}(F) \rightarrow ^4T_{2g}(F) \) and \( ^4A_{2g}(F) \rightarrow ^4T_{1g}(F) \) transitions respectively of the Cr(III) species [22,23]. Comparison of this spectrum with that of the authentic Cr(III) sample and the spectrum of the product mixture in the uncatalyzed reaction [15] clearly shows a blue shift which supports the existence of Cr(III) in the form of complex probably with PDA as evidenced by several researchers [24-27] with different catalysts. This is further confirmed from the colour of the product mixture which is purple in colour instead of the characteristic green colour of Cr(III).

3. RESULTS AND DISCUSSION

The linear rate of disappearance of Cr(VI) shows first-order dependence on [Cr(VI)] and the pseudo-first-order rate constants evaluated from the linear plots of log OD vs. time are given in (Table 1). The rate data show that the pseudo-first-order rate constant is found to decrease appreciably with increase in [Cr(VI)]. Similar type of rate retardation has been reported in the EDTA catalyzed Cr(VI) oxidation of phenylmercaptoacetic acid [28] and PA catalyzed Cr(VI) oxidation of DMSO [29]. This may be rationalized as dimerization of Cr(VI) oxidizing species at higher concentrations followed by decrease in concentration of active species.

The pseudo-first-order rate constants calculated for the variation of [PSAA] in the presence of PDA show a linear increase with increase in concentration of PSAA (Table 1). The non-constancy of \( k_2 \) values observed indicates that the order with respect to [PSAA] is not unity but fractional. The Michalis-Menten kinetics, eq.(2) with respect to PSAA for the PDA catalyzed reaction is proved from the linear \( (r = 0.999) \) double inverse plot of \( k_1 \) vs. [PSAA] with intercept on the rate axis. The values of \( k \) and \( K_m \) evaluated from the slope and intercept of the plot are \( 3.24 \times 10^{-3} \) s\(^{-1}\) and \( 1.19 \times 10^{-1} \) mol dm\(^{-3}\) respectively. The order with respect to PSAA is 0.79 ± 0.03 as revealed by the slope of the linear \( (r = 0.999) \) log-log plot of \( k_1 \) vs. [PSAA].

\[
    \frac{1}{k_1} = \frac{1}{k} + \frac{K_m}{k[PSAA]}
\]

3.1 Rate Dependence on Acidity and [PDA]

The effect of [H\(^+\)] on the rate of the reaction is studied by varying the concentration of HClO\(_4\) in the reaction mixture (Table 2) and found that the rate of the reaction increases with increase in [H\(^+\)]. Though a negligible effect of ionic strength is observed, it is maintained as constant in all the kinetic runs using sodium perchlorate.

To monitor the effect of [PDA] on the rate of the reaction, the kinetic runs were performed with varying concentrations of PDA from 0.5 × 10^{-2} to 40 × 10^{-2} mol dm\(^{-3}\). The rate of the reaction
increases linearly with increase in the concentration of PDA and leads to limiting value at higher concentrations of PDA (Table 2, Fig. 2). The reaction shows Michaelis-Menten kinetics with respect to [PDA], as shown from the linear plot \( r = 0.993 \) of \( k_1 \) vs. [PDA] not passing through the origin. This confirms the binding of PDA with the oxidizing species prior to the rate determining step. The Michaelis-Menten constant, \( K_m \), calculated from the slope and intercept of the above plot is found to be \( 5.36 \times 10^{-2} \) mol dm\(^{-3}\).

3.2 Effect of Temperature

In order to calculate the activation parameters for the PDA catalyzed reaction, the reaction is carried out at four different temperatures viz., 20, 25, 30 and 35°C and the overall rate constant values are presented in (Table 2). The thermodynamic parameters $\Delta^\ddagger S$ and $\Delta^\ddagger H$ are evaluated respectively from the intercept and slope of the Eyring’s plot of log $k_{\text{ov}}/T$ vs. 1/T. It is worthwhile to mention here that the observed magnitude of entropy of activation for the PDA promoted reaction is appreciably higher than that calculated for the uncatalyzed reaction [15] ($\Delta^\ddagger S = -24.5$ JK$^{-1}$ mol$^{-1}$) which follow the trend expected for the catalyzed reactions.

3.3 Linear Free Energy Relationship

The Hammett equation and its modified forms, all known as linear free energy relationships (LFER) have been found useful for correlating the reaction rates of meta- and para-substituted derivatives. A systematic study of LFER is made on PDA catalyzed oxidative decarboxylation with several para- and meta-substituted PSAs at 30°C to establish the effect of substituents on reactivity, to decide the nature of the transition state and the mechanism being followed. The introduction of electron-donating substituents in the para- and meta-positions of the phenyl ring of PSAA accelerates the rate appreciably while electron-withdrawing substituents decelerate the rate and the pseudo-first-order and the overall rate constants obtained are summarized in (Table 3). The Hammett plot (Fig. 3) examines the redox activity of Cr(VI) towards several substituents in the meta- and para- positions of the phenyl ring of PSAA and addresses the feasibility of the PDA catalyzed reaction with respect to them. Excellent correlation is obtained when log $k_{\text{ov}}$ are plotted against Hammett substituent constants, $\sigma$ with negative reaction constant, $\rho$. The negative $\rho$ value clearly demonstrates the involvement of electron deficient reaction center in PSAA in the slow step. The linear free energy correlation corresponding to PDA catalyzed reaction is:

$$\log k_{\text{ov}} = -1.05 \pm 0.03 \sigma - 2.05$$

\( r = 0.996; \ s = 0.025; \ n = 11 \)
An important point to be noted regarding the magnitude of $\rho$ value is that the observed $\rho$ value is smaller in the presence of PDA than in its absence [15].

### 3.4 Mechanism

Under the present experimental conditions of high $[H^+]$ and low [Cr(VI)], HCrO$_3^-$ species was proposed as the predominant form of Cr(VI) [14,15]. The increase in reaction rate with increase in concentration of $H^+$ with the ligand is in agreement with the existence of HCrO$_3^-$ species. In the presence of ligands it has been observed that the redox potential of Cr(VI) increases drastically [30,31] by forming complexes with them. In many ligand catalyzed reactions of Cr(VI) oxidation, the complex formed between Cr(VI) species and ligand is identified as reactive species and its oxidizing power is believed to be higher than free Cr(VI) ion.

The increase in reaction rate with increase in [PDA] in the present case may be attributed to the formation of kinetically active Cr(VI) oxidizing species, probably a bimolecular complex formed between HCrO$_3^-$ and PDA (Scheme 1, eq.5) and enhanced reduction potential of the Cr(VI)/Cr(IV) couple.
The spectral evidence for the formation of Cr(VI)-PDA complex \((C_1)\) is inferred from the substantial hyperchromic shift and broadening of the UV absorption peak of Cr(VI) (Fig. 4a) at 263 nm by the addition of PDA (Fig. 4b). The kinetic evidence for the reversible complex formation between PDA and HCrO\(_3^+\) is inferred from the Michaelis-Menten kinetics observed with PDA. The moderately low Michaelis-Menten constant value and the saturation kinetics observed with PDA (Table 2) demonstrate the existence of strong binding between HCrO\(_3^+\) and PDA in the bimolecular complex, \(C_1\).

The chromium atom of Cr(VI)-PDA complex \((C_1)\) then receives a nucleophilic attack by the sulfur atom of PSAA incorporating PSAA into \(C_1\) to form termolecular complex \((C_2)\). The development of positive charge on the sulfur atom of PSAA in the intermediate complex \((C_2)\) as a result of nucleophilic attack of PSAA is confirmed from the result of the reaction with different substituents in the phenyl ring of PSAA. The rate acceleration by electron-releasing substituents and retardation by electron-withdrawing groups in the para- and meta-positions can be explained on the basis of stabilization of the positive center on sulfur atom by electron-releasing substituents and destabilization by electron-withdrawing substituents. The supporting evidence for the formation of termolecular complex \((C_2)\) as a result of binding of PSAA with \(C_1\) is obtained from the perceptible change in absorbance at 351 nm (Fig. 4c).

The kinetic evidence for the formation of \(C_2\) is ascertained from the large negative value of entropy of activation observed in PDA catalyzed reaction (Table 2) as compared with the low value of entropy of activation obtained in the reaction without PDA [15] (-24.5 KJ mol\(^{-1}\)). This may be taken as an evidence for the association of PDA moiety in the transition state leading to the formation of more orderly rigid transition state. The linear plot between \(k_1^{-1}\) and [PSAA]\(^{-1}\) with definite intercept and non-integral kinetic order with respect to PSAA indicate that the ternary complex, [Cr(VI)-PSAA-PDA] is formed in an equilibrium step (eq.6). The Michaelis-Menten constant, \(K_m\) computed for the binding of PSAA with \(C_1\) also shows that the binding of PSAA with the active oxidizing species is moderately high. The complex \(C_2\) then experiences a redox decomposition slowly in the rate-determining step giving rise to the products Cr(IV)-PDA, CO\(_2\) and methylphenyl sulfone (Scheme 2, eq.7).

\[
\begin{align*}
H_2CrO_4 + H^+ &\rightarrow HCrO_3^+ + H_2O \quad (4) \\
HCrO_3^+ + PDA &\rightarrow \text{Cr(VI)-PDA} \quad (5) \quad (C_1)
\end{align*}
\]

**Scheme 1. Formation of active oxidizing species**

\[
\begin{align*}
\text{phenylsulfinyl acetic acid} + C_1 & \quad \overset{\text{fast}}{\longrightarrow} \quad \text{PSAA} + \text{Cr(IV)}-\text{PDA} + \text{CO}_2 \quad (6) \\
\text{slow} & \quad \overset{\text{slow}}{\longrightarrow} \quad \text{PSAA} + \text{Cr(VI)}-\text{PDA} + \text{CO}_2 \quad (7)
\end{align*}
\]

Scheme 2. Mechanism of PDA catalyzed redox reaction of PSAA and Cr(VI)

The Cr(IV)-PDA species formed in the reaction as a result of two-electron transfer participates in the faster steps [32] with Cr(VI)-PDA to give Cr(V)-PDA and consequently Cr(V)-PDA oxidizes another PSAA molecule and itself gets reduced to Cr(III)-PDA species. The Cr(V)-Cr(III) couple has a potential of 1.75 V which would enable the rapid conversion of Cr(V) to Cr(III) after the reaction with the substrate [33-35].

4. CONCLUSION

The PDA catalyzed redox reaction of phenylsulfinyl acetic acid and Cr(VI) follows Michalis-Menten kinetics with respect to PSAA as well as PDA. A mechanism involving reversible formation of a ternary complex, Cr(VI)-PDA-PSAA followed by a redox decomposition in the rate-determining step giving rise to the products Cr(IV)-PDA, CO₂ and methylphenyl sulfone is proposed. The substituent effect and linear free energy relationship are also discussed.
