ABSTRACT

This work evaluated the infra-red (IR) spectra of the oil extract from African nutmeg (Monodora myristica) seeds, popularly called ‘ehuru’ in the eastern part of Nigeria – among the Igbos. The microbial analysis of the dried ‘ehuru’ seeds was also carried out in order to ascertain the prevailing bacteria and fungi on the outer coat of this invaluable seed as sold in the market. Monodora myristica oil extract was obtained through soxhlet extractor using ethanol of Analar grade. About 15 g of the extract (oil) was obtained after assessing 400 g of the ground dried seeds

*Corresponding author: E-mail: eberechukwu.maduike@uniport.edu.ng;
of the sample. Infra-red analysis of the oil extract was evaluated. The IR spectra of the extract indicated that the sample contained the following functional groups: phosphate esters, ketones, amides, amines, amino acids, ammonium salts, alkenes, phenols, alkanes, ether, lactams and carboxyl groups. There is no doubt that the presence of these chemical functional groups in Monodora myristica seed conferred to its antimicrobial quality, therapeutic potentials, and its use as food additive (spice). Common microorganisms associated with the dried ‘ehuru’ seeds were bacteria - Streptococcus sp. and Staphylococcus sp.; fungus - mucor sp. The presence of these microorganisms on the seed might have been introduced as a result of exposure to unhygienic conditions by local handlers and frequent touching by buyers.

Keywords: African nutmeg; oil extract; IR spectra; functional group; microorganisms.

1. INTRODUCTION

African nutmeg (Monodora myristica) seed, popularly called ‘ehuru’ among the Igbo ethnic group in Nigeria is one of the commonly used spices in the eastern part of the country. It has the qualities of aromatic seasoning and flavour. It is only added to foods in small amount but it makes important contribution towards the aroma and flavour of foods due to the presence of the volatile oil (essential oil) and fixed oil. The seed is oblong and pale brown when fresh with a thin seed coat and hard kernel [1]. Monodora myristica is a flowering perennial edible plant which belongs to the family Annonaceae. It is commonly found in the West African evergreen forests in countries like Nigeria, Cameroon, Liberia, Angola and West Kenya [2,3]. The tree can grow up to a height of about 35 m and 2 m in diameter [4]. The plant starts fruiting between August and November [5]. The fruit M. Myristica is a berry of about 20 cm diameter; green and spherical, and becomes woody at maturity. The fruit is attached to a long stalk which is up to 60 cm long. Inside the fruit are the numerous oblong, pale brown seeds which are usually 1.5 cm long and are surrounded by a whitish fragrant pulp [6]. The oil extract from Monodora myristica seed contains significant pharmacological compounds like alkaloids, flavonoids, vitamin A and E as well as many vital lipids [7-10]. Traditionally, the plant is widely used especially to relieve toothache as well as in the treatment of dysentery. When roasted and ground, the seeds are rubbed on the skin for the treatment of skin diseases [11]. The seed is used by most Ethnic Nationalities in the various regions of Nigeria, as spice in the preparation of pepper soup (a traditional sauce used for health improvement for the healthy, sick and convalescing). Also, it is reported that natives in the Democratic Republic of Congo use it in the treatment of cough, headache, fever, and skin diseases. When ground to powder, it is used to prepare pepper soup as stimulant to relieve constipation and control passive uterine haemorrhage in women immediately after child birth. Traditionally, it has been used to cure mild fever and is known to have diuretic properties [12]. The aromatic stimulating properties of the plant appear to be the reason why it is occasionally used to ease flatulence, vomiting and for the correction of nausea arising from other drugs. Monodora myristica has been reported to exhibit antibacterial activity in vitro against some human and animal pathogens. This appears to be the bases for the use of the plant in traditional medicine to treat various diseases such as cough, pneumonia, tuberculosis, upper respiratory tract infections fever and skin diseases [12]. The oily extracts of Monodora myristica contain phytochemicals such as tannins, glycosides, sponins and Flavonoids which exert antimicrobial effects against Bacillus subtilis, Candida albicans and Staphylococcus aureus [13]. This work was targeted to ascertain the IR spectra of the African nutmeg oil extract and, thus the possible chemical substances present based on functional group. The research also aimed at finding out the possible microbial flora (bacteria and fungi) on the seed coat as sold in the market.

2. MATERIALS AND METHODS

2.1 Collection of Samples

The dried indigenous spice, Monodora myristica (ehuru) seeds were purchased from Ekeonunwa market in Owerri, Imo state of Nigeria. Identification and its authentication were done by Odum, D. C. of Department of Science Laboratory Technology (Biology/Microbiology), Federal Polytechnic Nekede, Owerri, Imo State, Nigeria.
2.2 Sample Preparation

The seeds were thoroughly screened to remove the bad ones and stones. The outer seed coats were removed and the good seeds were prepared by grinding them in a laboratory electric mill. The powdered sample was stored in an airtight, sterile glass container and kept in the refrigerator at 4°C until needed for analyses. Some seeds were kept whole (without grinding) for microbial analysis.

2.3 Extraction of Oil

Before extraction, 400 g of the powdered sample of M. myristica seed from the refrigerator was heated in a hot-air oven at 60°C in order to remove moisture (for easy extraction of the oil). The powdered seeds were soaked in 1000 ml absolute ethanol (99.9%, boiling range 78.0 - 78.5°C) for 48 hours. The extraction of the oil content of the seed was by soxhlet extractor. After the extraction, the solvent (ethanol) was removed from the extract through the fractional distillation process. At the end of the extraction, 15 g of the extract (oil) was recovered.

2.4 Infrared Spectroscopy

The infrared (IR) spectroscopy was carried out using the Philips Scientific, Model No: 40 13-15-17494 equipment at University of Uyo Research Laboratory, Akwa-Ibom State, Nigeria.

2.5 Microbial Analysis of the Seed

Nutrient agar (NA) medium was used for the isolation of bacteria on the seeds. This was achieved by aseptically rubbing and placing few of the seeds on the NA agar medium in triplicate plates and was incubated at 30°C for 48 hours. Some seeds were also placed on sabouraud dextrose agar (SDA) in triplicate plates for the isolation of fungi on the seeds. The plates were incubated at 26°C for 4 days. The bacteria isolated were characterized based on cultural characteristics, staining reactions and biochemical reactions as described by Cheesbrough [14], while the morphological characterization of the fungal isolates was through microscopy under lactophenol cotton-blue stain.

3. RESULTS AND DISCUSSION

The infrared (IR) spectroscopy of the oil extract from M. myristica was carried out and the spectra analysed following related authors’ guidelines [15,16]. Fig. 1 revealed the IR spectra of the oil extract from M. myristica seed while Table 1 showed the peak report.

Fig. 1. Infrared spectrum of oil extract from Monodora myristica seeds
3.1 Discussion

The presence of a hydroxyl functional group (-OH), which is bonded directly to an aromatic hydrocarbon (phenyl) ring. This makes them readily donate electrons to free radicals and stabilize them before they destroy living cells [18]. Due to the presence of the phenolic compounds, McCue and Shetty [19] and Etouchi et al. [20] reported that *M. Myristica* extract has the ability to exhibit anti-amylase activities which may be potentially useful in the treatment and management of diabetes mellitus and obesity. Also, the bactericidal and/or bacteriostatic effects of this seed as reported by Odoh et al. [21] and Ogu et al. [22] based on the findings of this study, is as a result of the presence of these phenolic compounds. It has been confirmed that *M. myristica* possesses vermicidal property [9]. This property can be attributed to the presence of phenol and phenolic compounds present in the seed (Table 1).

The study showed that this naturally endowed seed contains ketones (C=O). It has been reported that exogenous ketone supplements may provide benefits which include evident weight loss, athletic performance enhancement, anti-inflammatory properties and cancer prevention [23]. In a study to investigate how African nutmeg (*Monodora myristica*) lowers

3.1 Discussion

The results obtained from the infrared spectroscopy revealed that *M. myristica* seed contains important organic substances. Phenolic compounds were identified as the most naturally occurring group in the sample. The infrared analysis of *M. myristica* seed by Okwu and Njoku (2009) also showed the presence of phenol (hydroxyl phenol) [17]. These compounds possess a broad spectrum of biochemical activities including antioxidant and radical scavenging properties, and their antioxidant potential is believed to be conferred on them by the presence of a hydroxyl functional group (-OH), which is bonded directly to an aromatic hydrocarbon (phenyl) ring. This makes them readily donate electrons to free radicals and stabilize them before they destroy living cells [18]. Due to the presence of the phenolic compounds, McCue and Shetty [19] and Etouchi et al. [20] reported that *M. Myristica* extract has the ability to exhibit anti-amylase activities which may be potentially useful in the treatment and management of diabetes mellitus and obesity. Also, the bactericidal and/or bacteriostatic effects of this seed as reported by Odoh et al. [21] and Ogu et al. [22] based on the findings of this study, is as a result of the presence of these phenolic compounds. It has been confirmed that *M. myristica* possesses vermicidal property [9]. This property can be attributed to the presence of phenol and phenolic compounds present in the seed (Table 1).

The study showed that this naturally endowed seed contains ketones (C=O). It has been reported that exogenous ketone supplements may provide benefits which include evident weight loss, athletic performance enhancement, anti-inflammatory properties and cancer prevention [23]. In a study to investigate how African nutmeg (*Monodora myristica*) lowers...
chylomicrons and modulates lipid peroxidation in experimentally induced hypercholesterolemic male wistar rats by Nwozo et al. They reported that the extract was able to control the increase in body weight, thus observed reduction in body weight [6]. It is believed that these aromatic ketones (e.g., gingerol and paradol) give the seed its pungent and peppery taste [24]. Therefore, the African nutmeg seed can be harnessed as an exogenous ketone source for the benefit of mankind directly or indirectly.

Amines (N-H) are very essential in life because they are involved in creating amino acids. Amino acids are the building blocks of proteins in humans. Many vitamins are also made from amino acids. The amine groups which appeared at 3800-3000 cm⁻¹ indicate the presence of alkaloids [17]. It was reported by Okwu (2005) that alkaloids isolated purely from plant extracts and their synthetic analogues derivatives are potential medicinal agents used for fungicidal, bactericidal, antimalarial and analgesic purposes [25]. Amines are mostly used in pharmaceutical industries as analgesics (pain killers), decongestant (agent that relieves nasal congestion), and anaesthetics [26]. Thus, the oil extract from this organic seed can be refined and processed for amine production to be used in orthodox medicine.

The IR spectroscopy on the experimental seed revealed that it contains amino acids (N-H). As has been earlier said, amino acids are essential monomers in protein synthesis. It has also been reported that food supplements containing amino acids are good for children's growth, boost the immune system, protect the liver from toxic agents, regulate blood pressure, and accelerate tissue repair [27]. Significant reduction in the levels of serum total cholesterol and triglycerides in hypercholesterolemic rats treated with M. myristica oil extract has been reported [6]. This indicates that the extract possesses cholesterol lowering potential. These outlined benefits confirmed the use as a therapeutic agent in traditional medicine as reported by Cimanga et al. (2002) [12].

Ether (C-O-C) was another component of the oil extract from African nutmeg. Ether is a highly volatile and flammable liquid that has the ability to depress cerebral activity when used in anaesthetic dosage. Although in some individuals, ether causes irritation to the upper airway, it is a bronchodilator and it can be useful in treating bronchospasm resistant to other drugs [28]. This confirmed the use of Monodora myristica as a curative substance for respiratory tract maladies [12].

Alkane group (C-H) was another observable substance identified in the oil extract of the African nutmeg seed. An investigation study by Olga et al. (2017) involving the utilization of n-alkanes with an odd number of carbon atom as carbon sources by three yeast strain revealed high biomass yield, accumulation of high amount of lipids, and their ability to produce nutritionally important fatty acids [29]. A study with similar alkane group from the oil extract of the seed under investigation may likely produce the same result. Thus, studies to investigate the use of this oil extract to promote and/or achieve desirable traits and characteristics in organisms like fungi and bacteria should be encouraged.

Another functional group indicated in M. Myristica seed was the C-O stretching of ester centered at 1302-1034 cm⁻¹. Naturally occurring esters of organic acids in fruits and flowers give them their distinctive smells [30]. Esters with low molecular weight are commonly used as fragrances and found in essential oils. They are also used for food flavourings [31]. Plant esters as contained in M. myristica seeds have the ability to lower serum cholesterol by partially inhibiting the absorption of cholesterol in the small intestine [32]. The backbone of DNA molecules are made of phosphate esters hence will be beneficial to human physiological activities.

The reason for the isolation of very few microorganisms from the outer seed coat of M. myristica seed is not farfetched (Table 2). This is because an antimicrobial screening done by Adewole et al. [33] using the oil extract from M. myristica seed showed that the oil had antimicrobial action against Escherichia coli, Bacillus subtilis and Staphylococcus aureus. It was recorded that the antimicrobial activity exhibited by the oil extract competed favourably with the action of the antibiotic, streptomycin against these bacteria. A similar antimicrobial action on Staphylococcus aureus, Klebsiella pneumonia, Escherichia coli and Salmonella typhi was observed using ethanolic extracts of M. myristica seed [34]. The identified microorganisms might have been introduced on the seeds of 'ehuru' as a result of exposure to unhygienic conditions by handlers and frequent touching by buyers. It is, therefore, necessary that the seeds be properly
cooked before consumption. There is no doubt that the presence of these chemical functional groups in *M. myristica* seed conferred to it therapeutic, antimicrobial and industrial uses.

4. CONCLUSION

Having confirmed that the oil extract from *Monodora myristica* seed is of great value, large scale production of the seed should be encouraged so that its products like the oil extract can be channelled towards the production of pharmaceutical and personal healthcare products. Pharmaceutical industries are hereby encouraged to harness the great potentials of this nature’s gift to mankind. Also, the oil extract from this invaluable seed can be used in the right proportion as dietary supplements to promote healthy living. Therefore, the use of African nutmeg seed oil extract sold as spice, food supplement and health booster should be encouraged. Having seen the various chemical functional groups contained in *Monodora myristica* seed, it is very important that scientists, pharmacist, and dieticians utilize this natural product for antimicrobial, therapeutic, and nutritional purposes.
