Authors’ contributions

This work was carried out in collaboration between all authors. Author ST performed the experiments and wrote the first draft of the manuscript. Author JGN performed the second draft, statistical analysis and done all the corrections mentioned by the reviewers. Author RTN designed the study and wrote the protocol. All authors read and approved the final manuscript.

ABSTRACT

**Aims:** The present study was undertaken to explore in vivo antioxidant potential of ethanol extracts of *Nyctanthes arbor-tristis* leaf and stem in adjuvant induced arthritic rats.  
**Methodology:** Arthritis induced rats were administered with extract of *Nyctanthes arbor-tristis* leaf and stem. (150 mg/kg body Weight/rat/day for 30 days.  
**Results:** A significant decrease in paw edema was observed following oral administration of the leaf and stem extracts. A significant (p<0.05) increase in the level of tissue TBARS, GPx and catalase was seen in arthritis induced rats (group II) and NAT treated rats (group III and group IV) showed a significant decrease in lipid peroxides, GPx and catalase level to near normalcy. The activity of total tissue SOD was found significantly (p<0.05) low in arthritis induced rats (group II) while a substantial increase in the activity to near normal level was noticed in NAT administered rats. The alterations in hematological and other biochemical parameters were restored to near normal levels after a treatment period of 30 days. The structural changes of the tissues shows the therapeutic ability of *Nyctanthes arbor-tristis* stem and leaf in experimental animals which were further evidenced by
histological observations made on the hind limb tissue. 

Conclusion: As Nyctanthes arbor-tristis is of natural origin, it is a safe and effective intervention for free radical mediated diseases.

Keywords: Anti-inflammatory; Arthritis; In vivo antioxidant; lipid peroxidation; Superoxide dismutase.

ABBREVIATIONS

1. INTRODUCTION

Over 50% of all modern clinical drugs are of natural product origin and natural products play an important role in drug development programs in the pharmaceutical industry. Herbal drugs have gained importance in recent years because of their efficacy and cost effectiveness. Nyctanthes arbor-tristis L. (commonly known as Night flowering Jasmine) a shrub or a small tree growing to 10 m tall, with flaky grey bark. The seeds, flowers and leaves possess immunostimulant, hepatoprotective [1], antileishmanial, antiviral and antifungal activities [2]. The decoctions of leaves are extensively used by Ayurvedic physicians for the treatment of arthritis, obstinate sciatica, malaria, intestinal worms and as a tonic, cholagogue and laxative [2,3]. The water soluble portion of the alcoholic extract of leaves of N. arbor tristis (NAT) has been reported to possess anti-inflammatory activity in a variety of experimental models. In addition, analgesics, antipyretic along with ulcerogenic potency have also been observed [3]. Our previous study exhibits the in vitro anti-oxidant activity of N. arbor tristis leaf extract [4,5]. The arbortristoside A isolated from the seeds found to have antitumor activity [6].

Adjuvant induced arthritis (AIA) in experimental rats; a chronic inflammatory disease characterized by infiltration of the synovial membrane and associated with destruction of the joints resembles closely to the human rheumatoid arthritis [7]. The role of reactive oxygen species in the pathogenesis of degenerative joint disease has already been documented. Both steroidal and non-steroidal anti-inflammatory drugs currently used for the amelioration of the symptoms of the disease offer only temporary relief and often cause severe side effects like peptic ulcer and renal failure [8]. Therefore, new drugs without side effects are being studied all over the world as an alternate to NSAIDs and opiates [9]. Hence, the present study aims to investigate the in vivo antioxidant property and tissue defence mechanism of the leaf and stem extracts of Nyctranthes arbor-tristis in AIA by histopathological studies (20X).

2. MATERIALS AND METHODS

2.1 Plant Materials: Collection

Nyctanthes arbor-tristis (NAT-L (leaf) and NAT- S (stem)) were collected from Coimbatore
2.2 Preparation of the Plant Extracts

Collected materials were washed thoroughly; shade dried, powdered coarsely, and named it as NAT-L (leaf) and NAT-S (stem). The powder obtained (25 g) were extracted with ethanol (250 mL) in a Soxhlet extractor for 18-20 hrs. The extracts were concentrated using rotary flash evaporator and preserved at 4°C in air tight container. The yield from the extract was 12% for leaf and 10% for stem.

2.3 Test Animals

Male albino rats of Wister strain weighing around 160–180 g were procured from College of Veterinary and Animal Sciences, Mannuthy, Thrissur, Kerala for the present study. The rats were fed with commercial rat diet (Hindustan Lever Limited, Mumbai, India) and water ad libitum. The experiments were designed and conducted in accordance with the ethical norms. Once arthritis developed, food was served on the bottom of the cages as severely arthritic rats have difficulty in feeding from the cage top.

2.4 Induction of Arthritis

Arthritis was induced by a single intradermal injection of 0.1 ml of Freund’s complete adjuvant (FCA) containing 10 mg/ml dry heat-killed Mycobacterium tuberculosis per milliliter sterile paraffin oil (Difco Laboratories, USA) into a foot pad of the left hind paw of male rats [10].

2.5 Experimental Set Up

The optimum dosage of NAT S and NAT L were fixed as 150mg/kg based on previous toxicity studies. Animals were divided into four groups of six animals in each group as follows:

Group I - Control rats
Group II - Adjuvant induced arthritic rats
Group III - Arthritis induced rats administered with extract of NAT leaf. (150mg/kg Body Weight/rat/day for 30 days by intubations starting 10 days after adjuvant Injection)
Group IV - Arthritis induced rats administered with extract of NAT stem. (150mg/kg body Weight/rat/day for 30 days by intubations starting 10 days after adjuvant Injection)
Group V - Control rats administered with extract of NAT leaf (150mg/kg body Weight/rat/day for 30 days).
Group VI - Control rats administered with extract of NAT stem (150mg/kg body Weight/rat/day for 30 days).

2.6 Measurement of Paw Volume

The paw volume was measured using plethysmometer. During the experimental period, scoring of paw was restricted to once in a week to avoid excessive handling of the animals.
as this can reduce the severity or incidence of arthritis after adjuvant injection and the paw edema was calculated.

2.7 Collection of Blood and Tissue and Preparation of Tissue Homogenate

Animals were sacrificed on the day 30 by cervical decapitation; blood was collected with and without EDTA for plasma and serum separation. Joint cartilage tissue is removed immediately and these samples were used for further investigations. Joint cartilage tissue samples were homogenized in a solution of ice-cold 0.1 M Tris-HCl buffer (pH 7.4) at 4°C and centrifuged for 10 min at 15,000 g in 4°C [11].

2.8 Biochemical Assays

The hematological parameters like hemoglobin, RBC, WBC, Platelets, ESR, and PCV [12] were determined by usual standardized laboratory method. The biochemical parameters, blood glucose [13], urea [14], uric acid [15], creatinine [16], total protein [17], were also determined in serum. Marker enzymes such as glutamate oxaloacetate transaminase / aspartate aminotransferase (GOT/AST), and glutamate pyruvate transaminase/alanine aminotransferase (GPT/ALT), [18] ALP [19] and LDH [20] were analyzed.

2.9 In vivo Antioxidant Assays

Superoxide dismutase (SOD) was assayed by the method of Misra and Fridovich [21]. A 0.1 ml of tissue homogenate was added to the tube containing 0.75 ml ethanol and 0.15 ml chloroform (chilled in ice) and centrifuged. To 0.5 ml of supernatant, added 0.5 ml of EDTA solution and 1 ml of buffer. The reaction was initiated by the addition of 0.5 ml of epinephrine and the increase in absorbance at 480 nm was measured in in UV-Visible Spectrophotometer (Systronics UV-Visible Spectrophotometer 117, India). The enzyme activity was expressed as 50% inhibition of epinephrine auto oxidation/min. Glutathione peroxidase (GPx) was assayed by following Rotruck et al. method [22]. The reaction mixture consisted of 0.2 ml of EDTA, 0.1 ml of sodium azide, 0.1 ml of H2O2, 0.2 ml of reduced glutathione, 0.4 ml of phosphate buffer, and 0.2 ml of tissue homogenate was incubated at 37 °C for 10 min. The reaction was arrested by the addition of 0.5 ml of TCA and the tubes were centrifuged at 2000 rpm. To the supernatant, 3ml of disodium hydrogen phosphate and 1.0 ml of DTNB were added and the colour developed was read at 420 nm immediately. The enzyme activity was expressed as micromoles of glutathione oxidized/min/mg protein. The Catalase activity was measured by the method of Takahara et al. [23]. To 1.2 ml of phosphate buffer, 0.2 ml of the tissue homogenate was added and the enzyme reaction was started by the addition of 1.0 ml of H2O2 solution. The decrease in absorbance was measured at 240 nm at 30 sec intervals for 3 min. The enzyme blank was run simultaneously with 1.0 ml of distilled water instead of hydrogen peroxide. The enzyme activity is expressed as micromoles of H2O2 decomposed/min/mg protein. The level of Lipid peroxides was estimated using thiobarbituric acid reactive substances by the method of Ohkawa et al. [24]. To 0.2 ml of plasma, 0.2 ml of SDS, 1.5 ml of acetic acid and 1.5 ml of TBA were added. The mixture was diluted to 4 ml with water and then heated in a water bath at 95 °C for 60 min using glass ball as a condenser. After cooling, 1ml of water and 5ml of n-butanol/pyridine mixture were added and shaken vigorously. After centrifugation at 4000 rpm for 10 min, the organic layer was taken and its absorbance at 532 nm was measured in UV spectrophotometer. 1, 1, 3, 3-tetramethoxypropane was used as standard. The level of lipid
peroxides was expressed as n moles of TBA /100 g of tissue. The tissue homogenates were used for these studies.

2.10 Histological Studies

Hind limbs were removed and fixed in 10% buffered formalin. The tissue was sectioned to 4 µm thickness and subsequently stained with haematoxylin eosin for histological examination [25].

2.11 Statistical Analysis

All the grouped data were statistically evaluated with SPSS/10 software. Hypothesis testing methods included one way analysis of variance (ANOVA) followed by least significant difference (LSD) test. P values of less than 0.05 were considered to indicate statistical significance. All the results were expressed as mean ± S.D. for five experiments in each.

3. RESULTS AND DISCUSSION

Fig. 1 depicts the anti-arthritic effect of NAT-L and NAT-S on the changes in paw edema of control and experimental animals. Swelling and redness developed over a 24 h period in the foot injected with adjuvant. There was an appreciable increase in paw volume in group II rats. This inflammation reaction was then increased at that time when disseminated arthritis appeared and remains constant by the end of 3 weeks. A significant reduction in paw volume was observed in NAT-treated rats (group III and group IV) when compared with the arthritis-induced group (group II). Paw swelling is one of the major factors in evaluating the degree of inflammation and therapeutic efficacy of the drugs. Reduction of paw swelling from the third week onwards may be due to immunological protection rendered by the plant extract [26].

![Fig. 1. Paw volume changes in normal. Experimental rats. Y axis – Thickness of paw volume in mL, X axis - Weeks. Each point represents the mean ± S.D. for six animals in each group. Values are statistically significant at *p < 0.05; statistical significance was compared within the groups as follows: *a Arthritic rats compared with normal rats. *b NAT leaf and stem treated arthritic rats were compared with arthritic rats](image-url)
It was observed that there was no significant change in hematological parameters such as RBC, WBC, Hb, ESR, platelets, PCV and the changes in the induced group were reverted back to near normal levels on treating with NAT leaf and stem extracts (Table 1).

Values are expressed as mean±S.D. for six animals. Comparisons are made between: *a, Group I vs. Groups II; *b, Group II vs. Groups III and IV. The letters *a and *b represent the statistical significance at \( p < 0.05 \). NS: Non significant. In all the experiments there were no significant changes found in extract alone administered rats (Group V and Group VI).

The levels of blood glucose, urea, uric acid and creatinine of normal and experimental groups of rats are presented in Table 2. A significant \( p<0.05 \) increase in the levels of Glucose, urea and creatinine and decrease in uric acid level were observed in arthritis-induced rats (group II) when compared with normal rats. The increase in blood glucose in arthritic rats might be due to the decreased glycolytic and increased gluconeogenic enzyme activities, since impaired hepatic biosynthetic activities were reported in AIA condition [27]. The decrease in plasma uric acid in arthritic animals might be due to its continuous utilization by the system during free radical quenching reaction [28, 29]. Renal dysfunction might be the cause of raised blood urea and creatinine levels in AIA rats.

The letters *a and *b represent the Statistical significance at \( p < 0.05 \). In all the experiments there were no significant changes found in extract alone administered rats (Group V and Group VI).

A marked increase in the activity of membrane marker enzymes (AST, ALP, and LDH) and decrease in ALT were observed in the serum of arthritic rats (group II) when compared to control rats (Group I). Arthritic rats treated with NAT-leaf extract showed a significant \( p<0.05 \) change in the activity of membrane marker enzymes. Compared to NAT-S, NAT-L showed greater activity (Table 3). Assessment of the levels of AST, ALT, and ALP provides an excellent and simple tool to measure the anti-arthritic activity of the target drug. The activity of ALP was significantly increased in arthritic rats, since it is good index of liver and kidney impairment which is also considered a feature of adjuvant arthritis [30].

Values are expressed as mean ± S.D. for six animals. Comparisons are made between: *a, Group I vs. Groups II; *b, Group II vs. Groups III and IV. The letters *a and *b represent the statistical significance at p < 0.05. In all the experiments there were no significant changes found in extract alone administered rats (Group V and Group VI).

The activity of total tissue SOD was found significantly (p<0.05) low in arthritis induced rats (group II) than in control rats and a substantial increase in the activity to near normal level was noticed in NAT administered rats (Fig. 2). Activity was found to be higher in leaf extract (group III) than stem extract (group IV). The increased enzyme activity in NAT administered rats suggests a response of the animals against possible damage caused by oxygen free radicals. The superoxide radicals are the first product of molecular oxygen reduction. It acts as a catalyst for dismutations of superoxide radicals into H$_2$O$_2$ and into molecular oxygen to protect cells and tissues from superoxide radicals and other peroxides such as lipid peroxides in vivo [31].

Fig. 2. Effect of NAT-L and NAT-S extract on the antioxidant activity in normal and experimental rats. Values are expressed as mean ± S.D. for six animals. Comparisons are made between: *a, Group I vs. Groups II; *b, Group II vs. Groups III and IV. The letters *a and *b represent the Statistical significance at p < 0.05

Fig. 2 elucidates the significant (p<0.05) increase in the level of tissue TBARS, SOD and catalase in arthritis induced rats (group II) when compared to control rats (group I). The NAT treated rats (group III and group IV) showed a significant decrease in lipid peroxides, SOD and catalase level to near normalcy. Lipid peroxidation is considered as a critical mechanism of the injury that occurs during RA. Oxygen free radicals are potent lipid peroxidation-
inducing agents that cause the depletion of unsaturated fatty acids of the cell membrane, thus inducing loss of cell integrity and functional alteration of cell receptors and enzymes, in many diseases, especially rheumatoid arthritis, membrane damage often occurs in some organ or tissue, which provokes and accelerates the disorder structurally and functionally. The lack of antioxidant defense leads to an increase in lipid peroxidation and subsequent deleterious effects. In the present study, the increased lipid peroxides may be due to poor antioxidant defense system. Catalase, which decomposes hydrogen peroxide and protects the tissues from highly reactive hydroxyl radicals and also inhibits other long-chain peroxides. A significant increase in catalase activity in arthritis induced group as compared to the normal rats signifies over production of hydrogen peroxide. For a given concentration of catalase, the initial rate of hydrogen peroxide removal is proportional to the hydrogen peroxide concentration. Fig. 3 explains the activity of Glutathione peroxidase in control and experimental animals. The increased activity of GPx has been decreased in NAT leaf and stem treated animals. Glutathione peroxidase (GPx) is localized in the cytoplasm and mitochondria, which catalyses the degradation of various peroxides by oxidizing glutathione with the formation of its conjugates. GPx has more affinity than catalase for $H_2O_2$. GPx is essential for the conversion of glutathione to oxidized glutathione during which $H_2O_2$ is converted to water. The observed increase in the activity of GPx in joint tissue in arthritic rats indicate the increased $H_2O_2$ concentration and may help understanding the pathogenesis associated with arthritis [32-35]. In the previous study phytochemical screening of the extract of the leaves and stems of Nyctanthes arbor-tristis revealed the presence of flavonoids, tannins, saponins, glycosides, alkaloids, steroids, and phenolic compounds which act as free radical scavengers [4] to combat the disease.

**Fig. 3.** Effect of NAT-L and NAT-S extract on the GPx activity in normal and experimental rats. Values are expressed as mean ± S.D. for six animals. Comparisons are made between: *a, Group I vs. Groups II; *b, Group II vs. Groups III and IV. The letters *a and *b represent the Statistical significance at $p < 0.05$.
Histopathological examinations revealed that marked infiltration of leukocytes and eosinophilic inflammatory exudates in the synovial membrane Fig. 4 (Plate 1, Plate 2a, 2b, 2c, 3 and Plate 4). (Plate 1). Plate 1 shows joint tissue of control rats with synovial lining and normal joint space in between two articular cartilages (Group I). Plate 2a, 2b, and 2c illustrates Section of joint tissue of arthritis rats showing proliferation with granulation tissue adjacent to the damaged articular cartilage (group II). Sections studied show structure of skin. Dermis and deep tissues show dense lympho-plasmacytic infiltrates, vascular proliferation, vasculopathy (vessel wall damage), marked synovial hyperplasia with villiform appearance, well formed granulomas, occasional foreign body giant cells and sub synovial spindle cell hyperplasia.

Fig. 4. Histopathological examination of Normal, arthritis induced and *Nyctanthes arbor-tristis* treated rats

Plate 3 and Plate 4 show significant regeneration of synoviocytes and disappearance of inflammatory exudates, mild focal infiltration of cells in synovial region, few cuboidal cells lining the synovial membrane in NAT leaf and stem extract treated rat (group III and group IV respectively). In all the experiments there were no significant changes found in extract alone administered rats (Group V and Group VI).

4. CONCLUSION

Based on the results of the present investigation, it can be concluded that, ethanolic extract of *Nyctanthes arbor tristis* possess powerful *in vivo* antioxidant activity. Rats administered with NAT stem and leaf extract resulted in a significant improvement of oxidative status. The free radical scavenging activity of NAT-L was significant when compared to NAT-S. As NAT is of natural origin, it is a safe and effective intervention for free radical mediated diseases. Further, the isolation of the compounds responsible for the activity has to be taken up which
may result in a modern drug from this plant.
